# COGS 118A: Final Project Jiafeng Wu UCSD

#### Abstract

This paper builds upon Caruana and Niculescu-Mizil's 2006 study, *An Empirical Comparison of Supervised Learning Algorithms*, which evaluated the performance of various machine learning algorithms across multiple datasets and metrics. This study analyzes the performance of three algorithms—K-Nearest Neighbors (KNN), Decision Trees (DT), and Random Forests (RF)—on the Wine Quality, Abalone, and Student Performance datasets. Each model was optimized through hyperparameter tuning using grid search. The results demonstrate that Random Forest has best performance and test accuracy is higher when having more training data. These findings align with those of the original study.

#### 1. Introduction

Classification is an important application of machine learning. This study experiments on the performance of three classifiers—Decision Trees (DT), K-Nearest Neighbors (KNN), and Random Forests (RF)—using datasets with varying characteristics. The selected datasets—Wine Quality, Abalone Age Prediction, and Student Performance—represent variation in features, sample sizes, and distributions. All datasets were sourced from the UCI Machine Learning Repository. Inspired by Caruana and Niculescu-Mizil's work, this study aims to compare model performance based on accuracy, with metrics such as precision, recall, and confusion matrices to evaluate. The study also explores the effects of hyperparameter tuning and train-test splits on the performance of each model.

# 2. Methodology

This experiment evaluates the performance of three supervised learning algorithms using accuracy, precision, recall, and confusion matrix metrics. The datasets were preprocessed to handle missing values and ensure compatibility with the classifiers.

# Datasets:

1. Wine Quality Dataset has 4,898 samples and 12 features. Target variable (wine quality) is converted into a binary classification: scores ≥7 (high quality) and

- scores <7 (low quality). It is the largest dataset used in the study with imbalanced data.
- Abalone Dataset has 4,177 samples and 9 features. Target variable ("rings") is converted into a binary classification task: rings ≥10 (older) and rings <10 (younger).
- 3. Student Performance Dataset has 395 samples and 33 features. Target variable (G3, final grade) is transformed into a binary classification: scores ≥10 (pass) and scores <10 (fail). It is the small dataset used with imbalanced distribution.

Data preprocessing performs replacing for missing values and standardization using StandardScaler. Categorical variables in the Abalone dataset ("Sex") are encoded using LabelEncoder, and the Student Performance dataset uses one-hot encoding.

Learning Algorithms and Hyperparameters:

- 1. Decision Trees (DT) uses max\_depth (5, 10, 15) and min\_samples\_split (2, 5, 10).
- 2. K-Nearest Neighbors (KNN) uses n\_neighbors (3, 5, 7, 9), weights ("uniform" and "distance"), and p (1 for Manhattan, 2 for Euclidean).
- 3. Random Forest (RF) uses n\_estimators (50, 100, 150), max\_depth (10, 20, 30), min\_samples\_split (2, 5, 10), and max\_features ("sqrt" and "log2").

Hyperparameter tuning was conducted using GridSearchCV with five fold cross validation. The best parameters were chosen, ensuring optimal performance.

# 3. Experiment and Results

The results of the experiments are summarized in tables that show training, validation, and test accuracy, along with precision, recall, and error rates for all classifiers across the three datasets. Results demonstrate that Random Forest consistently performs better than Decision Trees and KNN across all datasets and partitions. An increase in test accuracy with additional training data is also observed.

Classifier	Train/Test Split	Train Accurac y	Training Error	Validation Accuracy	Validation Error	Test Accuracy	Test Error	Precision	Recall

	20/80	8688	524	1487	1058

**Table 2**. Confusion matrix across all conditions for the Wine Quality dataset.

## Wine Quality Dataset

Random Forest outperformed DT and KNN in two of the three partitions (Table 1). In the 80/20 split, KNN has the highest test accuracy of 87.28% with a test error of 12.72%, followed by Random Forest with 87.18% test accuracy and 12.82% test error. Decision Tree has a lower score, with 82.48% test accuracy and 17.52% test error. In the 50/50 split, Random Forest has the highest score with 86.32% test accuracy and 13.68% test error. KNN and Decision Tree followed, with test accuracies of 85.16% and 80.06%, respectively. In the 20/80 split, Random Forest again demonstrated better performance with 82.90% test accuracy and 17.10% test error. KNN and Decision Tree showed declines in this partition, having 81.26% and 79.23% test accuracies, respectively, indicating challenges dealing with reduced training data. Random Forest

consistently achieved the highest validation accuracy across all partitions compared to the others. It also has the best balance between precision and recall in the 80/20 split, with 80.54% precision and 57.60% recall, minimizing false negatives. In contrast, Decision Tree has lower performance, with precision of 55.07% and recall dropping to 37.04% in the 20/80 split, reflecting its difficulty with generalization. Random Forest had the lowest number of false negatives and false positives across all partitions (Table 2). For instance, in the 80/20 split, it misclassified 284 actual positives as negatives, compared to Decision Tree's 242 false negatives and KNN's 224. In the 20/80 split, Random Forest misclassified 1,487 false negatives, fewer than Decision Tree's 1,621 but slightly more than KNN's 1,402.

	20/80	3824	1221	977	4004

**Table 4**. Confusion matrix across all conditions for the Abalone dataset

#### **Abalone Dataset**

Random Forest showed the best results, having the highest test accuracy across all partitions: 80.26% (80/20), 78.96% (50/50), and 80.00% (20/80). Similarly, it has the highest validation accuracy among all. Decision Tree and KNN have lower validation and test accuracy, reflecting difficulties in dealing with the imbalance. Random Forest consistently achieved better precision and recall compared to the others, particularly in the 20/80 split, with precision of 76.0% and recall of 80.8%. Decision Tree and KNN demonstrated lower scores. However, KNN slightly outperformed Decision Tree in precision (76.5% vs. 74.3%), showing a better predictivity of the positive class. Random Forest had the lowest number of false negatives and false positives across all splits. In the 80/20 split, Random Forest misclassified only 208 false negatives, compared to Decision Tree of 253 and KNN of 238.

**Table 5**. Training, validation, and test accuracy, error, recall, and precision for DT, KNN, and RF across all partitions of the Student dataset.

Classifier	Split	Predicted Negative (Actual Negative)	Predicted Positive (Actual Negative)	Predicted Negative (Actual Positive)	Predicted Positive (Actual Positive)
DT	80/19	52	11	14	160
	50/50	149	40	33	372
	20/80	252	45	56	595
KNN	80/19	26	55	6	150
	50/50	85	93	54	362
	20/80	77	244	47	580
RF	80/19	71	8	19	139
	50/50	158	27	32	377
	20/80	220	88	39	601

 Table 6. Confusion matrix across all conditions for the Student dataset

#### **Student Performance Dataset**

Random Forest still has the best performance across all splits, achieving test accuracies of 88.61% (80/20), 90.07% (50/50), and 86.60% (20/80). KNN has lower performance especially in the 20/80 split with only 69.30% accuracy. Random Forest has high precision and recall across all splits. In the 80/20 split, it has precision of 94.61% and recall of 88.22%, reflecting its ability to correctly classify both passing and failing students. Decision Tree showed high precision of 93.58% and recall 91.95%.in 80/20 split. KNN exhibited the highest recall in the 80/20 split of 96.34%, but its precision dropped to 73.41%, indicating a higher number of false positives.

Algorithm/Dataset	Wine	Abalone	Student
-------------------	------	---------	---------

Decision Tree	0.825/0.813/0.975	0.768/0.782/0.865	0.895/0.888/0.971
KNN	0.873/0.864/1.000	0.790/0.791/0.938	0.753/0.781/0.848
Random Forest	0.872/0.873/0.999	0.803/0.798/0.953	0.901/0.926/0.996

Table 7. Test/Validation/Training Accuracy Table

From the summarization in Table 7, it is shown that Random Forest is the most robust classifier, demonstrating better generalization, higher accuracy, and better handling of imbalanced data compared to other methods. KNN achieves perfect training accuracy on the Wine dataset, which suggests it may completely memorize the training data. With a test accuracy of 87.3% and a validation accuracy of 86.4%, this indicates potential overfitting.

### 4. Conclusion

The experiment conducted across the three datasets shows the performance of the three classifiers. The results consistently demonstrated that Random Forest outperformed the other classifiers in terms of accuracy, precision, recall, and error rates across all train-test partitions.

Random Forest proves to be the most robust model, achieving the lowest error rates and maintaining a balanced precision and recall across all datasets. It minimizes both false positives and false negatives. Decision Tree shows low training error but higher test error, particularly in smaller training data such as the 20/80 split, which leads to reduced generalization and an increase in false negatives. KNN struggles with imbalanced datasets and performs less effectively with smaller training data. Overall, the findings align with prior studies, which have shown that Random Forest consistently demonstrates superior generalization and better performance across datasets. In addition, better test accuracy is seen in larger training data, 80/20 splits.

There are several enhancements to gain deeper insights into classification performance. Future studies could include more classifiers, such as Gradient Boosting Machines and Support Vector Machines, as this study evaluated only three classifiers. Addressing imbalanced datasets through techniques like the Synthetic Minority Oversampling Technique could also improve performance. Furthermore, using larger datasets could help better evaluate the classifiers' ability to discover more complex relationships. Finally, future studies could include additional evaluation metrics. While this study focused on accuracy, precision, recall, error rates, and confusion matrices, metrics such as F1 score and ROC curves would provide more assessment of classifier performance.
